

Fix for white edges:

This is a fix for the white edges caused by the plugin. You could use the adjustment clip function to forgo adding the fix to each individual clip. We use the blanketing fill effect to fix the edges. The effect is under the same menu for the DCTL transform.

After this, adjust the settings. You may have to change the crop up/down/left/right options based on your video resolution. The settings that I use are for my 1080p video. When adjusting the crop settings, make sure the same amount is used for each side.

If you want to copy and paste this effect as a profile, you can use the still options in resolve. Right click on the preview window (displaying the video preview) and press grab still. Save the file if you would like by right clicking the still in gallery. You can import the file to a different project by dragging the created file into the gallery window

Please don't forget that this will copy all your color grading data for the clip, so it is best to create a still before color grading
